

OPERATION and MAINTENANCE

MODEL 250 SERIES

Single Sideband Transceiver

INTRODUCTION

The Swan Model 250 Single Sideband Transceiver together with its accessories and optional equipment is designed to be used for SSB AM or CW communications in the 50-54 mc. amateur radio bands. MARS frequencies may also be covered by using the Model 405X oscillator accessory.

The Model 250 generates a single sideband signal by means of a crystal lattice filter, and the transceive operation automatically tunes the transmitter to the received frequency. When operating in single sideband mode, the normally used upper sideband (USB) is employed.

Basic circuitry of the single conversion design has been proven in several thousand of the popular Swan transceivers. Mechanical, electrical, and

thermal stability is exceptionally high. All oscillators are temperature compensated and voltage regulated. Push-to-talk operation is standard, with provision for plugging in the Model VX-1 accessory Vox unit for automatic voice control.

With a suitable power supply, operation may be fixed, portable, or mobile. Power input is rated at 240 watts, PEP, on single sideband, 180 watts on CW, and 75 watts on AM. The basic transceiver includes automatic gain control (AGC), and grid block CW keying.

Recommended power supplies are the model 117-XC for ac operation and model 14-117 for 12-volt dc operation.

SWAN
ELECTRONICS
Oceanside, California

SPECIFICATIONS:

FREQUENCY RANGE

50-54 mc. (except for a narrow segment at 53.5 mc)

POWER INPUT

Single Sideband, Suppressed Carrier:
240 watts, PEP, minimum.

CW:

180 watts, dc input.

AM (Single Sideband with Carrier):

75 watts dc input.

DISTORTION

Distortion products down approx. 30 db.

UNWANTED SIDEBAND SUPPRESSION

Unwanted sideband down more than 40 db.

CARRIER SUPPRESSION

Carrier suppression greater than 50 db.

RECEIVER SENSITIVITY

Less than 0.5 microvolt at 50 ohms impedance
for signal-plus-noise to noise ratio of 10 db.
Noise figure better than 3 db.

AUDIO OUTPUT AND RESPONSE

Audio output, 4 watts to 3.2 ohm load. Response essentially flat from 300 to 3000 cps in both receive and transmit.

TRANSMITTER OUTPUT

Wide-range Pi-network output matches antennas essentially resistive from 15 to 500 ohms impedance.

METERING

Power amplifier cathode current 0-400 ma. and 0-10 relative output indicator.

FRONT PANEL CONTROLS

Rec-Tune-CW, AF Gain, R.F. Gain, Mic. Gain, Carrier Balance, PA Plate Tune, PA Grid Tune, PA Load, KC Tuning Dial, MC Tuning Dial, Meter Switch.

REAR PANEL CONTROLS AND CONNECTORS

Bias potentiometer, CW key jack, Jones plug power connector, Vox connector, Antenna jack, Auxiliary relay switching.

POWER REQUIREMENTS

Filaments	12.6 volts, 4.5 amps, ac or dc
Relay	12 volts dc, 250 ma.
Bias	-110 volts dc, 100 ma.
Medium voltage	275 volts dc, 150 ma.
High voltage	800 volts dc, 300 ma. Peak Trans.

DIMENSIONS AND WEIGHT

Height	5-1/2 in.	Depth	11 in.
Width	13 in.	Weight	17-1/4 lb.

A. CIRCUIT THEORY

GENERAL DISCUSSION

The Swan 250 transceiver provides single sideband, suppressed carrier transceiver operation, and generates the single sideband signal by means of a crystal lattice filter. To permit a logical discussion of this mode of operation, certain definitions are necessary. In a normal AM signal (double sideband with carrier), a radio frequency signal is modulated with an audio frequency signal. This is considered by many to be merely a case of varying the amplitude of the carrier at an audio rate. In fact, however, there are actually sideband frequencies generated, which are the results of mixing the RF and the AF signals. These sidebands are the sum of, and the difference between the two heterodyned signals. In the detection of this conventional AM signal, the two sidebands are mixed with the carrier to recover and reproduce the audio intelligence. This is an inefficient means of transmission, because only 25 percent of the transmitted power is used to transmit intelligence. There are other attendant drawbacks, also. The bandwidth of AM voice transmission is approximately 6 kc, while the actual demodulated audio is only approximately 3 kc. The result is inefficient use of the frequency band, and over half of the allotted band is unusable due to heterodynes, interference, and congestion.

In the single sideband, suppressed carrier mode of transmission, only one of the sideband signals is transmitted. The other sideband and the carrier are suppressed to negligible level. In addition to increasing the transmission efficiency by a factor of four, single sideband effectively doubles the number of stations or channels which can be used in a given band of frequencies.

It should be remembered that in the single sideband, suppressed carrier mode of transmitting, the unwanted sideband and carrier are only suppressed, not entirely eliminated. Thus, with a transmitted signal from a transmitter with 40 db. sideband suppression, the other or unwanted sideband will be present, and will be transmitted, but its level will be 40 db below the wanted sideband. When this signal is received at a level of 20 db over S9, the unwanted sideband will be present at a level of approximately S5. The same is true of carrier suppression. With carrier suppression of 50 db, and a signal level of 20 db over S9, carrier will be present at a level of approximately S3 to S4.

In the Model 250 transceiver, the single sideband suppressed carrier signal is generated by the crystal lattice filter method. For details, refer to the schematic diagram and to Figures 1, 2, and 3.

SIGNAL GENERATION

When the push-to-talk switch on the microphone is pressed, the transmitter portion of the transceiver is activated, and it generates a single sideband, sup-

pressed carrier signal in the following manner. Carrier is generated by V14 Carrier Oscillator, which is a Pierce oscillator with the crystal operating in parallel resonance. This stage operates in both the transmit and receive modes. When transmitting, the RF output of the oscillator is injected into the control grid of the Balanced Modulator, V13. This balanced modulator is a beam deflection tube, and operates similar to a cathode ray tube in that the electron beam from the cathode is deflected to one output plate or the other by the charge appearing on the deflection plates. The carrier signal fed to the control grid of the balanced modulator appears on both plates of the output. The two plates are connected to Transformer Z1301 in push-pull, so the carrier signal cancels itself out in Z1301. The deflection plate DC voltages are adjusted by means of the carrier balance control so that the RF being fed to the output plates will cancel out, and the output from Z1301 will be zero. Audio signals from the Microphone Amplifier, V15, are applied as a modulating voltage to one deflection plate, and the two sidebands resulting from the sum and difference frequencies of the audio and carrier signals appear in the output of transformer Z1301. Carrier suppression is approximately 50 db.

The double sideband, suppressed carrier signal is then coupled from the secondary winding of Z1301 to the crystal filter, which suppressed the lower sideband, and permits only the upper sideband to be fed to the First IF Amplifier, V1. The carrier frequency is generated at approximately 10,698 kc.

The crystal filter is designed with a passband extending from 10,698.3 to 10,701.1 kc at the 6 db points. Thus, only audio modulation from 300 to 3100 cycles is passed by the filter.

Q1, the VFO 2N706 Oscillator, operates in the common base configuration as a Colpitts oscillator. Q2, the Emitter Follower is used for isolation and impedance matching purposes. The extremely good regulation achieved through using the Zener diode regulator D1601 across the bias supply voltage, also contributes to the stability. Q3 is a Buffer Amplifier stage which provides further isolation. The VFO in the Model 250 exhibits good stability after the initial warm-up period. Drift from a cold start will be approximately 2 kc for the first hour. After the initial warm-up period, drift will be negligible.

The single sideband, suppressed carrier signal from the First IF Amplifier is fed to the Transmitter Mixer, V2, where it is heterodyned with the VFO signal. The resultant signal at the desired transmit frequency is amplified by the Driver, V3, and the Power Amplifiers, V4 and V5. The signal from the VFO Amplifier is initiated in the transistorized VFO-Emitter Follower circuit Q1, Q2, and Q3. The signal from the VFO is routed to the VFO Amplifier.

FIGURE 1 BLOCK DIAGRAM, RECEIVE MODE

FIGURE 2 BLOCK DIAGRAM, TRANSMIT MODE

FIGURE 3 CRYSTAL FILTER, TYPICAL CHARACTERISTIC

1 MODEL 250 TRANSCEIVER

A. Circuit Theory (cont.)

TUNE AND CW OPERATION

Normally, the frequency of the carrier oscillator is approximately 300 cps outside the 6 db passband of the crystal lattice filter. In TUNE position, to enable the transmitter to be tuned to the maximum power output condition, the frequency of the carrier oscillator is moved approximately 500 cps to place it well within the passband of the crystal lattice filter. At the same time, one deflection plate of the balanced modulator is grounded, unbalancing the modulator and allowing full carrier input for tuning purposes. A similar procedure is followed for CW to allow full carrier output during CW operation. During CW operation, the cathode of V15A is disconnected from ground. This allows CW operation with no accidental audio modulation from the microphone.

RECEIVE

In RECEIVE position, or at any time when the transmitter is not in TRANSMIT, all circuits used in transmitting are disabled through the relay controlled circuits, K1, K2. The relays are energized for transmitting and de-energized for receiving. Relay K2, when de-energized, connects the antenna to the receiver input coils, L 601-602, and to the Receiver RF Amplifier, V6. The interstage coils, L603-604 couple V6 to the control grid of the Receiver Mixer, V7. The local oscillator signal from the VFO Amplifier is now used to heterodyne the received signal to the IF frequency. All IF amplification is accomplished at this frequency, nominally 10.7 mc, through V8 and V9 IF amplifiers. In the Product Detector V10A, the IF signal is heterodyned with the carrier frequency generated by Carrier Oscillator, V14. The resultant audio signal is then amplified by V10B, which then couples to V11, the AGC amplifier, and V12, the output audio stage.

FREQUENCY CALIBRATION

Frequency calibration of the Model 250 is in 5 kc increments on the 0-500 kc vernier tuning dial. Accuracy of this dial reading depends directly on the setting of the Megacycle Dial. When it is set to minimum frequency, (maximum tuning capacity), it will be at the 50 mc mark, and zero on the vernier dial will be 50 mc. Tuning the vernier dial will then change the frequency from 50 to 50.5 mc. Other .5 mc segments, (500 kc), are covered by turning the Megacycle Dial up in frequency in .5 mc steps.

Dial accuracy and tracking are quite good on the 250, but caution must always be observed when operating near band edges. Some means for measuring frequency is recommended. The optional calibrator kit will serve this purpose, and installs quite easily inside the transceiver.

TRANSMIT AND RECEIVE SWITCHING

Transmit and receive switching is performed by relays K1 and K2. In TRANSMIT position, only

those tubes that operate in the transmit mode are operative, all others being biased to cutoff through the relay contacts. In the RECEIVE position, with the relays de-energized, the tubes that are used only in transmit are cut off in the same manner. Relay K2 when de-energized, feeds signals from the antenna to the receiver, and is used also to control external switching circuits.

POWER RATING

The Swan 250 is capable of 240 watts, PEP input under steady state two-tone test conditions, when operated with any of the recommended power supplies. The peak envelope power, when voice modulated, is somewhat greater, typically 280 watts, or more.

Recommended power supplies produce a no-load plate voltage of approximately 925 volts. Under TUNE conditions, or CW operation, this voltage will drop to approximately 740 volts. Under steady state two-tone modulation, the voltage will drop to approximately 770 volts. If the power amplifier idling current is 50 ma, and the two-tone current, just before flat-topping, is 220 ma., the peak two-tone current will be 320 ma. Under these conditions the PEP input will be 770 volts time 320 ma, = 240 watts. Under voice modulation, because average power is considerably less, the power amplifier plate and screen voltages will be maintained higher, even during voice peaks, by the power supply filter capacitors. Peak plate current will therefore also be higher than with two-tone test conditions. Readings of cathode current will not reflect this power input, however, because of the damping in the cathode current meter. Cathode current readings under normal voice input should not exceed approximately 125 ma.

B. INSTALLATION

GENERAL

The Swan 250 transceiver has been designed to provide the utmost in ease of operation, stability, versatility, and enjoyment. Maximum enjoyment from your Swan will depend to a great extent on the installation. For fixed station or portable use, operation with the Model 117-XC power supply provides a compact arrangement with maximum ease of operation. All switching is performed in the transceiver. For mobile installations, the Model 14-117 supply provides similar switching arrangements, and speaker output may be fed through the car broadcast receiver speaker.

POWER SUPPLY

The Swan Models 117-XC or 230-XC Power Supplies provide all necessary voltages required by the transceiver for AC operation. The supplies come equipped with a pre-wired plug and cable, all ready for plugging into the transceiver. The Model 14-117 supply for mobile operation includes all necessary cables, connector plug, fuses, and installation hardware. The Jones plug for connection to the transceiver is furnished with the unit.

1 MODEL 250 TRANSCEIVER

B. Installation (cont.)

Power requirements for the Swan 250 are listed in the following table. Pin connections to the Jones type power connector are listed as an aid in connecting other brands or home-brew supplies.

EXTERNAL CONNECTIONS

Audio output from the transceiver is provided at pin 12 of the Jones plug. The other speaker lead goes to the common chassis ground at pin 6. Output impedance is between 3 and 4 ohms. For mobile installations, the car broadcast speaker may be used, in which case a DPDT selector switch should be installed to select the broadcast receiver or transceiver output. (See Figure 9.)

JONES PLUG CONNECTIONS

	Pin	Nominal	Minimum	Maximum
High Voltage	8	800 VDC 300 MA	600 VDC Low Pwr.	900 VDC Hi. Power
Medium Voltage	10	275 VDC 150 MA	225 VDC	325 VDC
Bias Voltage	3	-110 VDC 100 MA	-100 VDC	-130 VDC
Filament Voltage	4	12.6V* 4.5 amp	11.5 V	14.5 V
Relay Voltage	5	12 VDC 250 MA	10 VDC	14.5 VDC
*AC or DC				

MICROPHONE

The microphone input is designed for high impedance microphones only. The choice of microphone is important for good speech quality, and should be given serious consideration. The crystal lattice filter in the transceiver provides all the restriction necessary on audio response, and further restriction in the microphone is not required. It is more important to have a microphone with a smooth, flat response throughout the speech range. The microphone plug must be a standard 1/4 in. diameter three-contact type. The tip connection is for push-to-talk relay control, the ring connector is the microphone terminal, and the sleeve is the common chassis ground. The microphone manufacturer's instructions should be followed in connecting the microphone cable to the plug. With many microphones, the push-to-talk button must be pressed to make the microphone operative. For VOX operation, this feature may be disabled, if desired, by opening the microphone case and permanently connecting the contacts which control the microphone.

ANTENNA

Any of the common antenna systems designed for use in the 6 meter amateur band may be used with the Swan transceiver, provided the input impedance of the transmission line is not outside the capability of the pi-output matching network. The transmission line should be of the coaxial cable type. An antenna system should show a standing wave ratio of less than 2:1 when using 50 or 75 ohm coaxial transmission line. If open-wire or balanced type transmission line is used with the antenna, a suitable antenna tuner is recommended between the transceiver and the feedline. Various types of antennas are available from your dealer, and for the antenna builder, many are described in the amateur handbooks, also available from your dealer. Remember that even the most powerful transmitter is useless without a proper and efficient antenna system.

C. OPERATION

Before connecting any cables to the Swan 250 perform the following steps:

1. Rotate the PA BIAS control on the rear chassis apron, fully counter clockwise.
2. Rotate the REC-TUNE-CW located on the lower left of the front panel counter clockwise to REC.
3. Rotate the RF GAIN Control counter clockwise to operate the power switch to OFF.

POWER SUPPLY AND ANTENNA CONNECTIONS

1. Connect the 50 to 75 ohm antenna feedline to the coaxial connector on the rear chassis panel.
2. Connect the power supply cable to the Jones connector on the rear chassis apron.
3. Connect the power supply to the proper voltage source.

The Swan Model 250 may be operated from 117 volts, ac, 50-60 cycle power with the Model 117-XC power supply, or from 230 volts, 50-60 cycles with the Model 230-XC. The Model 250 may be operated from a 12 volt dc source with the Swan Model 14-117 power supply.

WARNING

DANGEROUS HIGH VOLTAGE IS PRESENT ON THE PLATE OF THE POWER AMPLIFIER WHENEVER THE POWER SUPPLY IS ENERGIZED. NEVER TURN POWER ON WHEN THE POWER AMPLIFIER COVER IS REMOVED. HIGH VOLTAGE IS ALSO PRESENT AT PIN EIGHT OF THE POWER PLUG.

RECEIVE OPERATION

1. Rotate the RF GAIN Control clockwise to full clockwise position. The power switch will operate applying filament, relay, bias, medium, and 800 volt high voltage to the transceiver.

CONTROL FUNCTIONS

ON-OFF SWITCH (On RF Gain Knob) Turns power supply on and off.	
REC-TUNE-CW	
Receive	All voltages are applied to transceiver.
Transmit (Push-to-Talk)	12 volt dc circuit through relay K1 and K2 is completed, and tubes used only in receive are biased to cutoff.
Tune-CW	All circuits for transmit are energized, as above, but one deflection plate of the balanced modulator is grounded, capacitor C1401 in the carrier oscillator is removed from ground.
MIC. GAIN	Controls potentiometer R1503 in the grid of V15A and controls amount of audio to the unbalanced modulator.
CAR. BALANCE	Controls potentiometer R1308 in the balanced modulator deflection plate circuit, and permits nulling out the carrier.
RF GAIN	Controls variable resistor R801, common in the cathodes

RECEIVER FUNCTION SWITCH

of RF Amplifier, V8 and V9 IF Amplifiers.

Changes receiver from SSB to AM mode and turns crystal calibrator on and off, if the calibrator kit is installed.

AF GAIN

Controls potentiometer R1201 in grid circuit of V12 AF Output, and controls audio volume.

VERNIER KC TUNING

Controls C1816 in frequency determining tank circuit of VFO.

MEGACYCLE TUNING

Controls C1811 in VFO.

PA GRID

Controls C105 in plate tanks of transmitter mixer and driver.

PA TUNE

Controls C415 on pi-network to tune final power amplifier plate to resonance.

PA LOAD

Controls C416 in pi-network to match impedance of output load. Tunes input to Receiver RF Amplifier.

2. Wait approximately one minute to allow the tube filaments to reach operating temperature. During this period, perform the following steps:
 - (a) Rotate MIC. GAIN fully counter-clockwise.
 - (b) Rotate CAR. BAL. control to the mid-scale position, with white dot on knob aligned with the long index mark on the panel.
 - (c) Preset PA PLATE control to mid-position.
 - (d) Preset PA GRID control to mid-position.
 - (e) Preset PA LOAD to mid-position.
 - (f) Set tuning dial to desired operating frequency.
 - (g) Set AF GAIN control to approximately 3 o'clock position.
 - (h) Set receiver function switch to SSB or AM, whichever mode is desired.
3. Adjust the PA GRID control for maximum receiver noise. Then tune across the band for signals.
4. The main tuning knob is labeled **FREQ. RANGE MC.** To tune the lower 500 KC of the 6 meter band, set this control to the 50 mc in-

dex mark. The vernier tuning dial, viewed through the window, will then read the low end of the band directly in kilocycles. To tune higher in the band, the main tuning control must be advanced .5 mc (500 KC) at a time.

A 500 KC calibrator kit is available from your dealer. When this is installed, it will prove useful in setting the main tuning dial to an exact 500 KC multiple. This calibrator is turned on by switching the receiver function control to the CAL. position.

NOTE: The vernier dial scale is adjusted to read correctly, plus or minus 10KC when tuning from 50 to 50.5 mc. Accuracy will be slightly less in the 50.5 to 51 mc range, and will gradually deviate, until at the high end of the band the vernier dial scale will not be accurate. With a 500 KC calibrator, any 500 KC multiple may be accurately determined.

CAUTION: If a calibrator, either internal or external of some type is not used, care must be exercised to stay within band limits. If you don't know exactly where the edge of the band is, allow plenty of margin. Remember that 50 to 50.1 mc is for CW only.

5. The 5th harmonic of the carrier oscillator will be heard at 53.49 mc and will make operation at this exact frequency difficult. Except for this one spot, the model 250 will provide complete band coverage.
6. A panel controlled noise limiter will reduce sharp impulse noise on both sideband and AM signals. Its effectiveness will vary somewhat, depending on the type of noise interference. It will not eliminate ignition noise, but will take the harsh edge off. In mobile installations, it will still be necessary to install ignition suppression and by-passing in the automobile engine.

RECEIVER TUNING—IMPORTANT, READ CAREFULLY.

Precise tuning of a single sideband signal is very important. Do not be satisfied to merely tune until the voice can be understood, but take the extra care of setting the dial to the exact spot where the voice sounds natural. Above all, avoid the habit of tuning so that the voice is pitched higher than normal. This is an unfortunate habit practiced by quite a number of operators. The following points help to explain the effects of mistuning:

1. If you tune so the received voice is higher than normal pitch, you will then transmit off frequency, and your voice will sound lower than normal pitch to the other station. He will probably retune his dial to make you sound right. If you keep this up, you'll gradually waltz one another across the band. If both of you are mistuning to an unnatural higher pitch, you'll waltz across the band twice as fast. (And someone will no doubt be accused of frequency drift.)
2. Mistuning results in serious harmonic distortion on the voice, and should be quite noticeable to the average ear. Some will claim that if they don't know how the other person's voice actually sounds, they can't tune him in properly, but this is not true. With a little practice, it will be fairly easy to tell. Some voices are relatively rich in harmonics, and are easier to tune in than a person with a "flat" voice. Also, a transmitter which is being operated properly with low distortion will be easier to tune in than one which is being overdriven and is generating excessive distortion. There is no mistaking when you have a station tuned right on the nose.
3. A vernier control for receive frequency, sometimes referred to as "incremental tuning," is not available on the Swan 250. Such a device is not necessary if proper tuning habits are exercised.
4. Your Swan 250 will automatically transmit on exactly the same frequency as the one to

which you are listening. There is no adjustment for making them the same, since by using the same oscillator for both send and receive, it happens automatically. If separation of receive and transmit frequency control is desired, the model 210 VFO unit may be used. The model 22 dual VFO adaptor must be installed in the 250 in order to accommodate the 210.

TRANSMITTER TUNING

CAUTION

The Model 250 covers frequency ranges outside the amateur bands. Care must be exercised not to transmit on these frequencies.

Tuning of the transmitter is not complicated, provided the few simple steps are followed in the correct order. Do not attempt initial tuneup without first performing the procedures for Receive operation described above. The following procedures assume that the unit has been checked out in Receive position, and a high impedance push-to-talk microphone is inserted in the MIC. JACK.

1. Set the meter switch to CATH. position.
2. Press Push-to-Talk to place unit in TRANSMIT, read the cathode current on the meter.
3. Quickly rotate the CAR. BAL. control on the front panel until the meter reads minimum cathode current.
4. Next, adjust the PA BIAS control on the rear of the chassis until the meter reads 40 ma.
5. Next, move the meter switch to OUTPUT position and set PA LOAD to 12 o'clock.
6. Set the CAR. BAL. to about 10 o'clock. Then, press the Mic. button and quickly adjust PA PLATE and PA GRID for maximum OUTPUT reading. Hold the Mic. button pressed just long enough to make these adjustments.
7. Switch to TUNE-CW position, and quickly adjust PA PLATE and PA LOAD for maximum OUTPUT reading. Tuning one of these controls will require re-tuning the other, so it will be necessary to adjust back and forth a few times in order to reach the maximum reading. This tuning step should be done quickly in order to avoid overheating the PA tubes. Generally, a limit of 20 seconds tuning time should be observed. If more time is required, switch back to REC. for a minute of cooling.

NOTE: We cannot overemphasize the importance of avoiding lengthy tune periods! 6146B tubes are quite expensive and can be damaged seriously in a short time if abused. Although the factory will honor all reasonable warranty claims, we cannot replace tubes which have been damaged due to excessive plate or screen grid dissipation. Examination of defective

tubes will be necessary before factory replacement can be authorized.

After tuning for maximum output, move the meter switch to CATH. position in order to observe PA cathode current. Switch to TUNE-CW position briefly to make this reading. When properly tuned, the PA cathode current will read between 200 and 250 ma. This will vary somewhat between sets and tubes, and will serve chiefly as an indication of a change in tube condition. If the reading drops off substantially, the 6146B tubes, as well as other tubes in the transmitter chain, should be checked.

NOTE: The OUTPUT meter reading is a relative measurement, and does not directly indicate output power. Feedline impedance and reactance will affect the reading substantially. Primarily, the OUTPUT meter position is intended as a means for tuning to maximum output.

9. For SINGLE SIDEBAND transmission: Leave the function switch in REC. position. Press the Mic. button and adjust CAR. BAL. for minimum output. Then advance the MIC. GAIN control and speak into the Mic. Set the control to the position where the average meter reading with voice modulation is about 125 ma. (Meter switch in CATH. position.) With the average microphone, the MIC. GAIN control will be set to 9 or 10 o'clock for close speaking. Avoid excessive MIC. GAIN setting, as this causes adjacent channel splattering and distortion.
10. For AM transmission: Tune the transmitter for maximum output, as described through step 8. Then, leaving the function switch in REC. position, press the Mic. button, and adjust CAR. BAL. for 80 to 90 ma. PA cathode current. Advance the MIC. GAIN control to the position where average voice modulation produces a slight upward flicker of the meter reading. Overmodulation will produce distortion on the transmitted signal.
11. For CW transmission: Tune the transmitter through step 8. Insert a key in the jack provided on the back of the set. Switch to TUNE-CW to transmit, and back to REC. for receiving. The transmitting frequency will be approximately 800 cycles higher than the receiving frequency. Thus, when two transceivers are tuned to the same frequency, they will hear one another on CW with an 800 cycle tone.

NOTE: The key jack requires a standard 1/4 in. diam., 2 circuit plug. If key clicks are noticeable on transmissions, a .47 or .5 mf capacitor of 200 volt rating may be connected across the key terminals for additional key click suppression.

D. ALIGNMENT AND TROUBLESHOOTING

RECEIVER SECTION:

1. Adjustment of double tuned RF and Mixer Coils, L601, L602, L603, L604. Feed 2 microvolts from a 50 mc signal generator into the antenna jack, and connect an AC Output Meter to pin 3 of the octal VOX socket. This is the high voltage plate terminal of the AF output stage. Adjust the 4 input coils for maximum output. Then, connect the antenna to the set, and adjust the antenna coil, L601, for maximum AF output, either on a signal or on antenna noise.
 2. Receiver RF Amplifier Neutralization. Improper neutralization of V6 will be apparent when adjusting L602, L603, and L604. These coils will normally tune quite broadly, unless neutralization is not correct, in which case, the coil adjustments will become rather sharp and critical, due to regeneration. If neutralization is far enough out of adjustment, there will be sudden changes in noise level when adjusting the coils, accompanied by birdie-like signals. The neutralizing capacitor is a mica trimmer, C604, located under the chassis next to L603. Adjust it carefully in the direction which reduces noise level and broadens coil tuning.
- NOTE:** With some antenna loads having reactive components or high SWR, it may be necessary to adjust neutralization slightly to reduce regeneration.
3. Adjustment of output IF coil, Z901 (located in front of V9). To peak this circuit, switch the receiver to AM mode, and adjust for maximum AF noise output.
 4. Receiver injection from the VFO amplifier tripler, V1-6EW6, is maximized by tuning L101, C104, and C105A. However, these are also transmitter adjustments, so normally they are not adjusted in receive mode, except to peak C105, the front panel control, (PA GRID) for maximum noise level.
 5. Loss of receiver volume or sensitivity will normally require tube testing. Voltages may be measured and referred to the voltage chart to trace possible failure of a resistor or capacitor. However, a high percentage of problems will involve one or more of the tubes. In the received circuitry, these will be: V1, V6, V7, V8, V9, V10, V11, V12, and V14.

FREQUENCY CALIBRATION, APPLIES TO BOTH RECEIVE AND TRANSMIT MODES:

The Megacycle Dial is C1811, and is set to exactly maximum capacity when tuning the lower 500 KC of the 50 mc amateur band. The Vernier Tuning Dial is C1816, and it is calibrated in kilocycles from zero to 500. On the right side of the VFO compartment are

two locking type trimmers. The top one is C1812, and is used for setting dial calibration. The lower one is C1814, and it is adjusted only when temperature compensation needs to be changed. A frequency calibrator is required before adjusting C1812. The 500 kc crystal calibrator kit which is available for installation in the 250 may be used for this purpose.

CALIBRATION PROCEDURE:

1. Set C1811, the megacycle dial, to maximum capacity. Determine this by moving a signal on the kilocycle dial as far up the 0-500 dial scale as possible. In other words, as the MC dial is turned toward greater capacity, it will cause a given signal to move upward on the 0-500 kc scale. Rock the MC dial back and forth, until it is determined that maximum capacity has been reached. The index line on the MC dial will be quite close to the 50 MC panel index at this time.

NOTE: The MC dial is purposely made to turn quite hard, since it will not be moved very often and will not want to be bumped out of adjustment. Tension may be relieved, or tightened further, by means of the No. 6 Allen screw set in the aluminum bearing block located between the panel and the MC knob.

2. After the MC dial has been set to maximum capacity, tune for the 50 MC calibrator signal on the 0-500 kc dial. It should come in at zero on this dial. Adjust the VFO trimmer, C1812, so it does.

Note that with this calibration system, the frequency cannot be tuned below 50 mc as long as the KC dial is not tuned below the zero index. Adjustment of the mc dial can only move the frequency up higher in the band. This is the reason for wanting to make sure the MC dial is set exactly at maximum capacity before setting C1812.

After the above calibration adjustment has been made, the MC dial will read approximately correct. As it is moved up in .5 mc steps (500 kc steps), the KC dial will tune 50.5 to 51 mc, 51.5 to 52 mc, etc. Accuracy of the KC dial, however, will be most nearly correct in the 50-50.5 mc range. It will be quite close in the 50.5-51 mc range, and then will begin deviating to where in the 53.5-54 mc range it will be useful primarily as a logging scale. With the 500 kc calibrator, any 500 kc point can be accurately determined, and other frequencies can be closely interpolated.

OPERATION BELOW 50 MC

For certain MARS frequencies, it will be desirable to provide for operation below 50 mc. This can be done by adjusting the VFO trimmer, C1812, so that

the 50 mc index mark on the MC dial is actually 49.5 mc. After the mc dial has been set to exactly maximum capacity, locate the 50 mc calibration signal on the KC dial, as previously described. But, instead of adjusting C1812 so that 50 mc comes in at "zero" on the KC dial, gradually "walk" the 50 mc signal up to the 500 index mark on the KC dial by carefully moving C1812. The 49.5 mc harmonic from the 500 kc calibrator will now be found by tuning the KC dial down to "zero." The MC dial will now be offset by .5 mc, and 50 mc will actually be at the 50.5 index, etc.

TRANSMITTER ADJUSTMENTS

ADJUSTMENT OF CARRIER FREQUENCY

- A. With dummy load and output meter attached, tune transceiver for maximum output.
- B. Null out carrier with PTT pressed and set resting plate current to 40 ma with bias pot.
- C. Connect AF generator to MIC JACK, adjust MIC. GAIN full CCW.

Procedure:

1. With AF generator at 1500 cps, increase MIC. GAIN to produce a 75 ma reading on the meter.
2. Adjust Z801 for maximum meter reading.
3. Adjust both top and bottom cores of Z1301 for maximum meter reading.
4. Adjust MIC. GAIN for meter reading of 200 ma.
5. Set AF generator to 300 cps. Adjust C1402 for meter reading of 75 ma.

PA NEUTRALIZATION

1. Connect a dummy load to the antenna jack.
2. Set PA tune and PA load controls to 9 o'clock, and frequency to approximately 50.2 mc.
3. Press Mic. button, insert a small amount of carrier with the Car. Bal. control, and adjust PA grid for maximum PA cathode current. Then adjust Car. Bal. control for 100 ma meter reading. Do not hold Mic. button pressed for more than a few seconds during this adjustment.
4. With the Mic. button pressed, and the PA cathode reading 100 ma, slowly turn the PA tune control from 9 o'clock to 3 o'clock. A smooth resonance dip should be observed, with no rise or peak occurring on either side of the dip. If a peak is noticed, adjust the PA neutralizing capacitor, C414, in the direction which eliminates the peak.

DRIVER STAGE ADJUSTMENTS

1. Driver coils, L101, L201, L301. Set frequency to 50.2 mc, and PA grid control to 10 o'clock. Press the Mic. button, and insert carrier for about 100 ma PA cathode reading. Tune PA plate for resonance dip.
2. Adjust L101, L201, L301 for maximum meter reading.
3. Driver coil tracking has been factory adjusted and will not normally require further adjustment. If operation at the high end of the 6 meter band is required, and output power drops excessively, tracking can be adjusted by turning mica trimmers C104 on the VFO amp., and C206 on the transmit mixer stage. The trimmers should be peaked at the high frequency end, and the coil cores at the low end, with these adjustments repeated back and forth in the usual manner until proper tracking is achieved.

TROUBLESHOOTING GUIDE	
DEFECT	POSSIBLE CAUSE
PA IDLING CURRENT UNSTABLE	1. Defective 6146B 2. Defective Bias Potentiometer 3. Defective Bias Supply
INABILITY TO LOAD TO 200- 250 MA	1. V2, V3, V4, V5 Defective 2. Driver Stage Improperly Tuned 3. Trans. Mixer Improperly Tuned 4. VFO Amplifier Improperly Tuned 5. Antenna Not Resonant at Frequency 6. Defective Transmission Line
INSUFFICIENT CARRIER SUPPRESSION	1. Carrier Balance Control Improperly Adjusted 2. Defective 7360 Balanced Modulator 3. Carrier Oscillator Frequency Incorrect
INSUFFICIENT SIDE-BAND SUPPRESSION	1. Excessive MIC. Gain 2. Incorrect PA Load Adjustment. 3. Carrier Oscillator Frequency Incorrect
MICROPHONICS IN RECEIVER	1. Z901 Improperly Tuned 2. V14, V10, V8, V7, or V6 Defective
LOW RECEIVER SENSITIVITY	1. Pa Grid, Plate, or Load Improperly Set 2. Bandswitch Improperly Set 3. K2 Back Contacts Defective 4. V6, V7, V8, V9, V10, V11, V12 Defective

G. POWER SUPPLIES

GENERAL DESCRIPTION:

The Swan Universal Power Supply systems are designed to provide all necessary voltages required by Swan Transceiver models 240, 250, 300-C, 350, and 400. The model 117-X basic A.C. supply is designed for an input of 117 volts at 50 or 60 cycles. The model 230-X is identical except that it operates with either 117 or 230 volts. For fixed station use, the 117-X or 230-X is installed in a cabinet which matches the Swan transceivers. This cabinet also contains a speaker, phone jack, and indicator light. The complete combination is designated as model 117-XC or 230-XC. The A.C. line cord plugs into the back of the supply. In the 230-XC, provision for changing from 117 to 230 volts input is made by simply changing line cords. Wiring changes are taken care of in the line cord plug.

12 VOLT OPERATION:

A D.C. Module attaches to the back of the A.C. supply and converts it for 12 volts D.C. input. the model 14-X D.C. Module is for negative ground systems, the most common type. (For positive ground systems, the model 14-XP D.C. module is available.) The combined units are designated as model 14-117 or 14-230 depending on which A.C. supply is used. The positive ground models are designated as model 14P-117 or 14P-230.

With the versatility of this power supply design, a number of advantages become apparent. The D.C. supply may be operated from an A.C. line by detaching the D.C. module, making a simple wiring change, and plugging in an A.C. cord. (See instructions under "Mobile Installation.")

The matching A.C. supply, model 117-XC or 230-XC, may be converted easily to 12 volts input by attaching the 14-X D.C. module to the back. This provides for portable or emergency operation from a 12 volt battery. There may also be times when it will be desirable to operate temporarily in an automobile, such as during a vacation trip, field day, or emergencies. The 117-XC can be set on the floor or front seat, and with the 14-X attached it becomes a 12-volt power supply, complete with speaker.

SPECIFICATIONS:

Power Rating: 200 watts average, 500 watts peak.
Input:

Model 117-X: 117 volts nominal, 50-60 cycles
Model 230-X: 230 volts or 117 volts, 50-60 cycles.
Model 14-X: 13 volts D.C. nominal, 40 amps peak.

Output:

800 volts at 200 ma. average, 600 ma. peak.
275 volts at 150 ma. continuous.
110 volts negative bias, at 100 ma.
12 volts D.C. at 200 ma., relay supply.
12.6 volts A.C. at 5.5 amps. (with A.C. input only)

Fig. 6. MODEL 117-XC
AC POWER SUPPLY WITH SPEAKER

Fig. 7 MODEL 14-117
DC POWER SUPPLY

Battery Drain with Swan Transceiver

Rec: 3.5 amps. Trans: 16 amps average, 40 amps peak (not including filament drain of transceiver).

DESIGN:

Both the A.C. and D.C. sections are conservatively designed for long, reliable service with a minimum failure rate. At the same time, they are designed for easy access and servicing for those times when it is required. Any component can be readily checked out and replaced in a matter of moments. The D.C. module and A.C. supply can be detached quickly from one another and tested individually, thus isolating the source of trouble.

The A.C. supply is quite conventional, using a silicon rectifier bridge for the medium voltage, and another for high voltage. The 117-X has a single primary winding for 117 volt input, while the 230-X has a pair of primary windings which connect in parallel for 117 volts, and in series for 230 volts. The switching is taken care of in the A.C. line cord plug.

The D.C. module uses two power transistors for switching in a flip-flop oscillator circuit. A large portion of the cost in this unit is in the transistors where no compromise has been made. They are rated at 60 amperes, with a 45 volt rating. A diode spike clipping circuit provides additional protection against one of the common sources of transistor failure.

MOBILE INSTALLATIONS READ CAREFULLY

The 12 volt electrical system in an automobile will sometimes generate high voltage transients. This can be caused by the starter motor, the alternator or generator, or loose wiring, and can represent a serious hazard to the transistors in your DC power supply. By selecting the best transistors available for the application, your Swan supply is capable of absorbing a good deal of abuse, but there is a limit to what even the best transistors can take and for this reason we strongly urge that you read the following notes completely, and follow them carefully.

- (1) Clean and tighten the battery terminals and clamps.
- (2) Tighten battery cables where they attach to the starter solenoid and engine block.
- (3) Inspect battery cables for corrosion or wear. Replace them if they look questionable.
- (4) Check battery condition frequently. If the cells do not hold a similar charge or water level, replace the battery.
- (5) Check alternator, (or generator), and regulator connections for tightness. Also, primary ignition wiring, horn wiring, lights, etc.
- (6) Check the charging voltage from the alternator. Often the regulator is misadjusted, and the voltage setting may be excessive. It should not read more than 14.5 volts at normal engine speeds.

POWER SUPPLY INSTALLATION:

- (A) Connect the primary leads from the power supply directly to the battery terminals. Mount the ceramic fuse block with 50 amp. fuse in series with the positive lead. (With positive ground systems, the fuse goes in the negative lead). If possible, drill and tap a hole in the battery post itself for a contact stud. The more intimately the supply is connected to the battery, the less chance there is for voltage transients to reach it. Solder lugs are provided for the ends of the various leads.
- (B) The filament line comes prewired to the Jones plug, and has an in-line 9 amp. fuse. Connect this line to the ignition switch accessory terminal, as recommended in the schematic, Fig. 8. In most cars the 12 volts at this terminal is switched off while twisting the ignition key to start the engine. Thus, the relay in the power supply will also be switched off, and the transistors will not be subjected to the sharp transients put out by the starter motor. NOTE: The car radio is normally connected to the accessory terminal for the same reason. It may be more convenient to locate the 12 volt line going to the car radio, and splice into it with the transceiver filament line. Look for

FIG. 8 MODEL 14-X D.C. MODULE

the car radio fuse, and connect to this circuit on the "hot side".

POWER SUPPLY PROTECTION—A Zener diode is installed in the Swan 14-X DC module for added protection. It is an 18 volt Zener which connects across the input terminals of the power supply. It conducts only when the input exceeds 18 volts, thus has no effect on normal operation. Transient voltage pulses which go beyond the 18 volt level will be absorbed by the diode, thus preventing them from reaching the transistors. This protection will be effective so long as the diode is operative. If transients reach a high enough level, or a long enough duration, the diode will eventually fail, and literally burn out. After this, the transistors are on their own, and will most likely fail for the same reason. (See Warranty Policy)

SPEAKER CONNECTIONS: Speaker leads coming from the Jones plug go to an under dash speaker, or to a speaker selector switch which may be installed as illustrated. Another arrangement which works well is to install a rear seat speaker for the car radio, and then connect the front speaker only to the transceiver.

FIG. 9 MODEL 117-X (230-X) POWER SUPPLY

A.C. OPERATION: The 12 volt power supply may be operated from an A.C. line by two methods.

- Detach the D.C. Module, and plug in an A.C. line cord in place of it. Before applying power, disconnect the brown cable wire going to terminal (1) of the A.C. supply and connect a jumper from terminal (1) to (2). Temporarily tape the brown wire to keep it from shorting to ground, since it will be carrying 12 volts D.C. Now the power supply will operate when the A.C. line is plugged in, although the transceiver filaments will still be operating on the battery. This arrangement will be useful primarily for checking out the A.C. portion of the supply when trouble shooting.
- To operate the transceiver entirely on the A.C. line, it will be necessary to do the following: Disconnect the 5 wire cable going from the the transceiver to the A.C. portion of the supply. Replace it temporarily with a 10 wire cable and hook-up as illustrated in the schematic diagram Fig. 9. This is the same cable and speaker hook-up used in the matching cabinet, 117-XC. Using the D.C. supply in this manner will prove useful for portable or

emergency operation from the car when A.C. power is available.

If frequent A.C. as well as D.C. operation with the mobile supply is contemplated, both the 5 wire and 10 wire cables may be connected simultaneously to the supply. Thus, when operating on D.C., the 5 wire cable is plugged into the transceiver, and on A.C. operation the 10 wire cable is used.

MATCHING CABINET:

Ordinarily the A.C. supply will be purchased complete in a matching cabinet as either model 117-XC or 230-XC. However, in some cases an owner may have purchased a 117-X or 230-X basic supply only, perhaps in a D.C. supply combination, and he may wish later on to mount it in a matching cabinet. For this purpose the cabinet with speaker and cables is available separately. The basic A.C. supply mounts inside with three screws, and the pre-wired cable connects as shown in the schematic. Connections to the phone jack and speaker have already been made. Two leads from the indicator light must be run through the grommet and soldered to the terminals provided at the bottom of the

FIG. 10 MODEL 14-X, D.C. MODULE
INTERNAL VIEW

supply. Refer to the schematic for clarification. The A.C. line cord is also provided with the matching cabinet kit. These line cords are available separately also, and come normally wired and stamped for 117 volts. 230 volt line cords are also available on special order, or the 117 volt line cord may easily be wired for 230 volts by referring to the schematic. Note that the 230 volt line cord will work only with the 230-X basic A.C. supply. The 117 volt line cord will work with either the 117-X or 230-X.

POWER SUPPLY

WARRANTY POLICY—The normal guarantee on your Swan power supply is for a period of 90 days from date of purchase, and covers all components, material and workmanship. In the case of transistor failure, however, the warranty on them will be void if inspection proves that high transient voltages from the automobile were responsible. We will do all in our power to be fair and just in this determination. The warranty card must be filled out and mailed to the factory within 10 days from date of purchase. Do not ship a unit to the factory for servicing without prior authorization. Check with your dealer first, as he may be in a position to handle the service work more quickly. This warranty is void if the equipment has been misused or damaged.

PLUG IN VOX ACCESSORY, MODEL VX-1

OPERATING INSTRUCTIONS

1. Place the VOX-PTT switch in the PTT position and adjust the transceiver for normal push-to-talk operation.
2. Plug in the VX-1 and rotate the VOX GAIN, ANTI-VOX, and DELAY controls fully counter-clockwise. Attach the top of the VX-1 to the 350 back with a G-32 screw.
3. Rotate the transceiver MIC. GAIN fully counter-clockwise. This will prevent audio from being transmitted but will not affect VX-1 during initial adjustments.
5. Place the VOX-PTT switch in the VOX position.
6. While speaking into the microphone in a normal manner, slowly rotate the VOX GAIN control clockwise until the VX-1 keys the transmitter. Do not use more VOX GAIN than necessary to assure positive operation at normal voice levels.
7. Increase the receiver gain until received signals are at a normal volume level. These

signals will trip the Vox when picked up by the microphone.

8. With the microphone held in the normal operating position, very slowly increase the ANTI-VOX until received signals do not trip the Vox.

NOTE: Excessive ANTI-VOX gain will cause received signals to gate the VX-1 off so that no amount of sound at the microphone will key the transmitter. Satisfactory balance between the VOX GAIN and ANTI-VOX is easily obtained when the microphone is at least a foot from the speaker.

9. Adjust the DELAY control to hold the transmitter keyed for the desired interval after you stop talking.

NOTE: A little experimenting on the air will reveal that only a small portion of the first spoken syllable is lost when the VX-1 is actuated. Short DELAY settings will result in most efficient operation.

SWAN MODEL 210 FREQUENCY CONTROL UNIT

SWAN MODEL 210 FREQUENCY CONTROL UNIT

Model 210 Frequency Control Unit is designed for full coverage of the 50-54 mc band when used with the model 250 transceiver. The unit matches the 250 in height, depth, and styling. Telay switching is built-in, and a selector knob on the front panel provides for selection of frequency control. In position 1 the VFO in the 250 is used for both transmit and receive. In position 2 the 250 VFO is used for transmit and the external 210 VFO is used to receive. In position 3 the 210 VFO is used for both transmit and receive.

An adaptor socket must be installed on back of the 250 transceiver to accommodate the 210. This adaptor socket and installation kit is included with the 210. See page 24 for details.

CIRCUIT THEORY

Q1, the 2N706 Oscillator operates in the common base configuration, as a Colpitts oscillator. See Figure 6. Capacitors C1801, C2001, and C2003 effectively tap the oscillator across only about 10 percent of the tank circuit. This results in exceptional stability. Q2, the Emitter Follower, is used for matching the impedance of the coaxial cable to the transceiver, as well as for isolation. The KC tuning dial provides vernier tuning over a 0 to 500kc range, and the MC dial is adjusted to cover the desired range.

ALIGNMENT

For frequency calibration of the model 210 external oscillator, refer to page 11 for instructions on calibration of the internal VFO in the model 250 transceiver. The same procedure applies to the model 210. Actual oscillator frequency is listed in the accompanying chart.

Transceive Frequency	Injection Freq. From VFO Amp.	Oscillator Frequency
49.5 MC	38,802 KC	12,934.0 KC
50.0	39,302	13,100.6
50.5	39,802	13,267.3
51.0	40,302	13,434.0
52.0	41,302	13,767.3
53.0	42,302	14,100.6
54.0	43,302	14,434.0

FIG. 15

MODIFICATION INSTRUCTIONS, for installation of Model 210 outboard VFO socket in Swan 250 Transceiver.

1. Install the pre-wired socket in the accessory location on the back of the 250. Be sure to secure the mounting screws tightly.
2. Remove coax. running from eyelet "E" of the VFO circuit board to base terminal of Q3. Connect center conductor of new coax. "A" to base terminal of Q3, and its shield to ground lug, as illustrated.
3. Connect center conductor of new coax. "B" to eyelet "E" of VFO circuit board. Connect its shield to ground lugs as illustrated.
4. Remove and discard the wire lead going to term. lug "T" on the circuit board, and connect the new gray wire to lug "T".
5. Connect the Red, Orange, Blue, and Green leads as illustrated.
6. Connect the new 4000 ohm 5-watt resistor to term. lugs R-R as illustrated.
7. The Model 210 VFO may now be plugged into J6.

SCHEMA

Swan 250 Modification Information

The purpose of this package is to pass along sources of information for modifications to improve the performance and convenience of operation for the Swan 250 6M transceiver. Some of the listed mods are from the factory, some from various ham magazines and others are from the author's own experience with these units.

The following mod sheets are available from the Swan factory:

- (1) Modification of receiver front end in units manufactured prior to July 25, 1967 (If last two digits of serial number are 12 or less and not followed by letter "B", mod is recommended for better receiver performance.)
- (2) "S" meter addition. (Circuit is similar to that used in 250C. 250C meter is available from factory at a cost of \$15 plus shipping in late 1977. Modification requires the use of aux relay contacts normally used for activation of linear amp.)
- (3) CW sidetone. (Also requires use of aux relay contacts and switch on rear panel.) (More on this later.)
- (4) Break-in CW. (Requires that you have accessory VOX module.)
- (5) Instructions for installation of crystal calibrator.

For those who are curious as to the differences between the 250 and the 250C, here are the ones found by the author:

- (1) "S" Meter
 - (2) Improved front end using cascode nuvistors.
 - (3) Built-in provision for inclusion of VOX accessory without modification.
 - (4) USB/LSB selection
 - (5) Locking Mhz dial
 - (6) 6JH8 gated beam balanced modulator
 - (7) Function & mode switching rearranged
 - (8) Provision for noise blanker
 - (9) Elimination of AGC switching in I.F. amp. (Freeing that set of relay contacts for the "S" meter circuit.)
- (Not responsible for any changes missed.)

The following mods have been made to my own Swan 250:

- (1) -10V regulation was tightened as outlined in the TV-2 2M transverter manual. This mod consists of changing the value of R1601 & R1602 to 500 ohms each. Mod also calls for adding .01 Mf bypasses to pins 4,5, and 10 of the power plug. This mod is primarily for use of the TV-2 with the Swan 250 but is also suggested any time additional load is to be placed on the -10V supply.
- (2) Regulation of relay supply voltage tightened by removing 4.7 ohm resistor in the relay supply circuitry of the 117-XC supply, and replacement of the 200 PIV 1A diode with a heavier unit. (I used a 12A unit here but 3A or 6A would probably be O.K.) This was done for two reasons. #1: As you

K1LPS - May '78

L. L. FILBY
P. O. BOX 13
W. DANVILLE, VT. 05873

may note above, some mods call for use of relay contacts. The addition of an extra relay, especially when using the TV-2, caused unreliable operation of the relays. Relay voltage was being pulled down to 6V under load. #2: Various solid state preamps were tried and required a power source. Although considered bad practice, the relay supply, with additional filtering (1000 Mf), zener voltage limiting (12V), and heavy bypassing, was used to supply preamp voltage. More about preamps later. The additional relay incidentally, was afixed to a clear spot under the chassis with RTV.

- (3) MC dial variable capacitor was replaced with a fixed 20 pf S.M. unit inside the VFO box. This was a highly significant change and to demonstrate what I mean, remove the cabinet cover, tune in a steady CW signal such as your calibrator or other stable signal source. Blow on that MC dial variable and listen to your signal jump 'way out in left field. Picture the same situation in a drafty room or other situation where the ambient temperature is not stable. This mod has increased the frequency stability greatly. Be prepared to recalibrate the dial by adjusting C1812. Unless you're prepared for a lot of confusing cut-and-try, it would be advisable to leave the frequency/temperature trimmer, C1814, alone. Both trimmers affect calibration. If someone has moved C1814, have fun. This mod sacrifices frequency coverage except for the bottom 500 Khz but in view of current band usage this is no problem.
- (4) Besides poor frequency stability, one of the biggest problems with Swan 250's (250C's too.) is poor carrier suppression. My unit was no exception when I bought it. Various individuals have come up with improvements. (K5EFW, QRP July '77 H & K; WB8GLA, Ham Radio Oct. '76.) Either of these two mods will offer some improvement to the carrier suppression problem. WB8GLA suggests matched 1% resistors in the balanced mod circuit among other things. In my case I simply hand picked matched values for R1302/R1303, R1305/R1309 & R1306/R1310. This did improve balance some. However, not to be overlooked is proper adjustment of the carrier oscillator. The procedure outlined in the instruction manual is an excellent method. Don't take the frequency of the crystal too literally. Adjust for response as outlined in the manual. I found this adjustment to go a long way toward getting the residual carrier suppressed. And don't ask for carrier suppression checks from the guy down the block. As pointed out in the manual, if the signal is 40 over S9, even a carrier 50 db down is going to be heard. One final item on the front panel carrier null adjustment. I have found that nulling for minimum indication on the plate meter is too crude for really effective nulling. I have a sensitive SWR indicator in the line and when adjusting for null, I turn the bridge sensitivity pot full up and make my final nulling adjustment. I have had many, many complimentary comments on the quality of my signal particularly with regard to stability and carrier suppression.
- (5) CW Sidetone. I'm using a CW sidetone circuit that was written up by K1KXA in the June '72 Ham Radio, Ham Notebook. It was originally intended for the Swan 350 but works identically in the 250 series. Schematic, PC layout and instructions are included on an attached sheet. It works beautifully and does not require an additional switch for disabling during SSB operation as is required by the circuit furnished by Swan. It does require that you keep a CW key plugged in, or just a dummy phone plug. I prefer to keep the CW key plugged in because you need it for the "tune" operation.

- (6) I'm using the "S" meter mod provided by Swan. This circuit is a bit crude but it does give some semblance of an "S" meter reading and it is simple to incorporate. For those who would like to have a more sophisticated circuit, the amplified "S" meter article by K6SDX in the March '75 Ham Radio magazine is recommended.
- (7) Comments on receiver sensitivity and preamps. Although I have used several preamp designs with the Swan 250, in the end I have settled for not using one. The front end of the original 250, using a single 6NA5 is adequate for 6M. However, it is imperative that you keep the tubes up to snuff and the circuit properly adjusted, particularly neutralization. I happen to have noise figure measuring equipment and after playing around with a number of preamps, ended up with a noise figure of 3 db with the stock circuit. 3 db is far more than necessary at 6M as the noise floor for six is approximately 9 db. The 250's could probably use more overall gain but as with any receiving system, the front end is not the place to get it. A lot depends on your particular operating situation. I do a lot of contest mountaintopping with my 250 and found that all preamps got me was a lot of intermod problems. To make a long story short, they shouldn't be necessary but feel free to try one. I've used a Hamtronics unit using J-308 J-FETs and a 40673 dual gate MOSFET unit from the ARRL Handbook. If you really want the best out of the Swan 250's, or any VHF receiver, you are reminded that adjusting for best noise figure is the only way to go and adequate noise figure is relatively easy to come by at 6M. Speaking of noise figure and its measurement, I did install a switch on the rear panel of the 250 so I could disable the AGC. You simply ground the AGC line at the junction of R806/R901. Disabling the AGC is a necessity for any meaningful measurement of noise figure. The 250 here is used as the tunable I.F. for the TV-2 and it was desired to measure the noise figure of that system too.
- (8) Miscellaneous: If your 7360 (V13) should go bad, you can substitute the 6JNE as used in the 250C. But... you must rewire the socket as these two tubes are not pin-for-pin replacements. Price 7360's and you'll see why you might want to do this. (If you can find them that is.)
